Parenteral Nutrition in Infancy and Childhood Hans Bode, 2013-11-21 A tranquil mind puts flesh on a man English proverb After a period of relative neglect nutrition as a medical science is now an area of great clinical and investigative activity This renewed interest in clinical nutrition derives in large part from observations suggesting that early nutritional deprivation not only interferes with the maintenance of health growth and resistance to disease but if present during critical periods

of central nervous system development may also cause permanent impairment of intellectual capacity. Studies on brain development during malnutrition have continued to demonstrate the vulnerability of the developing brain to nutritional insult. Winick 1968 has emphasized that nutritional deficiency occurring while cells of the central nervous system are actively dividing results in a permanent decrease in central nervous system cell number. Later nutritional deficiency which results in decrease in cell size appears to be recoverable. Perhaps even more important than effects of malnutrition on brain cell number is the effect on brain protein synthesis and myelination. As different regions of the brain grow at different rates and human cerebellar and cerebral cell number increase for the first few months of life, newborn nutritional deficiency may compromise brain development. Dobbing 1973 has focused attention on the vulnerability of the brain to nutritional insult during the brain growth spurt which occurs around the time of birth. In the human this period extends throughout the third trimester of pregnancy and into the second postnatal year.
