Role Of Aging In Atherosclerosis The Sequestration Hypothesis:

The Role of Aging in Atherosclerosis R.E. Tracy, 2003-05-31 The cover of this book summarizes the central features of the sequestration hypothesis. Commonplace appearances seen in human coronary artery fat stained in paraffin sections by a new technique explained in Chapter Eleven are arranged to suggest pathways of evolution toward atheroma. The hypothesis formulated and defended in the pages of this book is this: Fibroplasia progresses upward in column a from 1a to 3a as a characteristic feature of aging. This starts sooner and progresses faster in men than in women. Numbers of SMCs remain essentially constant so that fibroplasia per SMC steadily increases. The rise upward conveys an increasing propensity to sequester atherogenic lipids causing transition rightward into column b. Sequestered extracellular lipid then attracts fatty streak elements especially foam cells and lymphocytes to propel the arterial site rightward into column c. Frame 1c corresponds to the AHA Lesions Committee classification type IIb, the progression-resistant fatty streak arising directly without prior lipid sequestration; this can progress to atheroma but slowly after much delay, although extreme provocation can accelerate the process. Such progression is rightward toward atheroma with thin cap, not upward toward fibroplastic thickening. Frame 2c corresponds to the AHA classification type IIa, progression-prone fatty streaks. These readily evolve into atheroma again by horizontal progression.
