Lysosomal Cysteine Proteases:

Lysosomal Cysteine Proteinases and Their Role in Visceral Yolk Sac Mediated Nutrition and Embryotoxicity

Jeffrey Lee Ambroso, 1994 *Role of Proteases in the Pathophysiology of Neurodegenerative Diseases* Abel Lajtha, Naren L. Banik, 2007-05-08

Researchers seeking problems that offer more hope of success often avoid subjects that seem to be difficult to approach experimentally or subjects for which experimental results are difficult to interpret. The breakdown part of protein turnover in vivo particularly in nervous tissue was such a subject in the past it was difficult to measure and difficult to explore the mechanisms involved. For factors that influence protein metabolism it was thought that protein content, function and distribution are controlled only by the synthetic mechanisms that can supply the needed specificity and response to stimuli. The role of breakdown was thought to be only a general metabolic digestion/elimination of excess polypeptides. We now know that the role of breakdown is much more complex; it has multiple functions, it is coupled to turnover and it can affect protein composition, function and synthesis. In addition to eliminating abnormal proteins, breakdown has many modulatory functions: it serves to activate and inactivate enzymes, modulate membrane function, alter receptor channel properties, affect transcription and cell cycle, form active peptides and much more. The hydrolysis of peptide bonds often involves multiple steps, many enzymes and cycles such as ubiquitination and often requires the activity of enzyme complexes. Their activation, modification and inactivation can thus play an important role in biological functions with numerous families of proteases participating. The specific role of each remains to be elucidated.

[The Role of Lysosomal Cysteine Proteases in Endocytosis-mediated Retinal Degeneration](#) Ronald D. Kinser, 2012

Many retinal degenerative diseases result in blindness. The causes and clinical progression of these diseases are heterogeneous in nature. In many instances the genes involved are known yet the molecular mechanisms leading to blindness still require elucidation. Our lab utilizes the *norpA* mutant which undergoes light dependent retinal degeneration as a cell death model. Previous characterization of *norpA* has shown that rhodopsin and arrestin form stabilized complexes that are internalized into the cell body in response to light. Furthermore, this mass endocytosis of rhodopsin leads to its aggregation and accumulation in the late endosome. Accumulation of proteins in the endosomal system has been shown to lead to the permeabilization of endosomes and lysosomes, subsequently allowing translocation of the resident cathepsins to the cytosol. Cathepsins are lysosomal proteases that have been shown to mediate cell death when translocated from the endosomal system. In this thesis I describe the role of the lysosomal cysteine proteases in endocytosis mediated retinal degeneration. Using a combination of techniques in genetics, cell biology and biochemistry we show the specific involvement of the cathepsin L like protease CP1. Retinal degeneration in *norpA* retinas can be blocked by mutation of the *Cp1* gene or expression of the pan cysteine cathepsin inhibitor cystatin. Conversely, retinal degeneration can be accelerated in *norpA* retinas by overexpressing CP1. Interestingly, there is a decrease in CP1 immunofluorescence accompanied by a decrease in rhodopsin colocalization in the *norpA* mutant compared to wild type, suggesting a CP1

redistribution event in norpA retinas in response to light We also examined cathepsin involvement in a broader range of neurodegenerative disorders Although cahepsins were not implicated in many we discovered a role for cathepsins in the retinal degeneration observed in Drosophila trafficking mutants This suggests that cathepsins may be involved in a broader group of retinal degenerative disorders caused by defects in endosomal trafficking Lastly we identified a novel role for the Toll signaling pathway in endocytosis mediated cell death as mutations to Toll and dorsal block retinal degeneration These data represent a novel molecular pathway leading to cell death in Drosophila A potential link between Toll activation and cathepsins function is discussed

Proteases in Apoptosis: Pathways, Protocols and Translational Advances Kakoli Bose, 2015-08-06 This book provides a comprehensive overview of the proteases involved in programmed cell death It presents a focused yet extensive discussion on proteolytic enzymes such as caspases HtrAs granzymes calpains and cathepsins as well as laboratory protocols related to enzymology and apoptosis Mouse model systems and non invasive imaging techniques in apoptosis related diseases such as cancer and neurodegeneration are also covered in this book While slowly unravelling the complexities of apoptosis in chapter one the next three chapters individually elaborate on different classes of proteases that play key roles in the initiation progression and execution of programmed cell death The last two chapters complete this discussion by describing different laboratory methodologies and therapeutic advances involving apoptotic proteases Protocols portraying in vitro and ex vivo colorimetric and fluorescence based enzyme kinetic studies as well as cell death assays are explained in the fifth chapter Preclinical in

vivo models and non invasive imaging in apoptosis to understand the complexities of disease progression and their contribution toward therapeutics is recounted in the last chapter The book spans topics related to both fundamental and applied biology It would therefore be equally appealing and informative to scientists working in the field of apoptosis and those who are investigating mechanisms of proteases and enzymes in general The protocols would certainly benefit both graduate and undergraduate students working in the related fields and provide useful leads for drug design to translational biologists involved in neurodegeneration and cancer research

Proteases: Structure and Function Klaudia Brix,Walter Stöcker,2014-01-21 Proteolysis is an irreversible posttranslational modification affecting each and every protein from its biosynthesis to its degradation Limited proteolysis regulates targeting and activity throughout the lifetime of proteins Balancing proteolysis is therefore crucial for physiological homeostasis Control mechanisms include proteolytic maturation of zymogens resulting in active proteases and the shut down of proteolysis by counteracting endogenous protease inhibitors Beyond the protein level proteolytic enzymes are involved in key decisions during development that determine life and death from single cells to adult individuals In particular we are becoming aware of the subtle role that proteases play in signaling events within proteolysis networks in which the enzymes act synergistically and form alliances in a web like fashion Proteases come in different flavors At least five families of mechanistically distinct enzymes and even more inhibitor families are known to date many family members are still to be studied in detail We have learned a lot about the diversity of the about 600 proteases in the human genome and begin to understand their physiological roles in the degradome However there are still many open questions regarding their actions in pathophysiology It is in this area where the development of small molecule inhibitors as therapeutic agents is extremely promising Approaching proteolysis as the most important irreversible post translational protein modification essentially requires an integrated effort of complementary research disciplines In fact proteolytic enzymes seem as diverse as the scientists working with these intriguing proteins This book reflects the efforts of many in this exciting field of research where team and network formations are essential to move ahead
