

Managing stored grain

In the third of a four part series, Milling and Grain takes a closer look at the management of stored grain

by Kirk Nelson, Director of Marketing and Sales, Behlen Mfg. Co., USA

Even with proper ventilation, grain can only be stored for a limited time. It will deteriorate based on temperature and moisture content increases. The allowable storage time is based on the length of time grain can be stored before losing 10.5 percent of dry matter. While this amount of dry matter deterioration is assumed, it is assumed that the grain loses some quality.

For each 10° F (3° C) increase in temperature, storage time is cut roughly in half when held at a given moisture content. Grain moisture content will change with relative humidity of the surrounding air and the grain temperature. Contact your local extension office for detailed information on stored grain.

Under certain conditions, no matter how long the grain is stored, grain may not reach the desired moisture content that will allow it to be stored without spoilage. Keep in mind that air temperature and relative humidity are not constant. Use the daily average for determining final moisture content.

It is recommended for wet climates where storing grain for short periods in a wet building leads to various moisture problems. If no aeration is provided, grain may deteriorate much faster due to regions of higher temperatures that may begin to develop, producing heat and moisture that accelerate deterioration. The purpose of aeration is to reduce high temperature areas and to keep all grain at a constant temperature.

Grain storage

Grain spoilage can occur due to improper storage and management. One very common problem is that the grain moisture content is too high for the storage period. On it may

have been held too long without adequate aeration prior to drying. Alternatively, it may not have been allowed to cool properly after drying. It must be dry and cool before storing. Even after this, aeration continues to be vital to control grain temperature.

Several fundamental problems may simply be poor initial grain quality, including pockets of insect infested kernels, weed seeds and trash which restrict airflow and provide food for insects and insects. And of course, it is essential to properly control the insects themselves.

Whatever else you do, grain must be checked on a periodic basis during storage.

The moisture content of grain storage

The length of time grain can be stored without aeration and the moisture content at which it is stored determines whether there will be significant deterioration. Short-term storage generally refers to winter storage. Long-term storage spans more seasons. You should contact your local extension office for recommended moisture contents and storage times.

Grain should be dried to the moisture content required for the intended storage period and the type of grain stored. If test results, an accurate moisture test is needed to determine if the grain is dry enough.

Grain temperature

An aeration system is necessary for controlling grain temperature in order to prevent grain loss. But aeration is not drying. A drying fan can be used for cooling of grain to stored so that the bulk is in draft. But if grain is so hot that it is a different bin, it should be equipped with an aeration system to control the grain temperature during storage. It is imperative that the grain be cooled during storage to control insects and
