In many engineering applications adhesively bonded and bolted connections serve similar purposes. The load ranges for applicability, however, depart at the high end of the load spectrum. Ease of reversibility also provides an advantage with the bolted connections. Due to these advantages bolts and nuts are still a preferred method of joining, especially in power transmitting components, in the automotive industry. Sealing performance, and durability are important issues in such joints and they should be an important part of the design process. Papers included in this symposium address the related topics of washer properties, interface configuration in multiple bolt connections, and thermal stresses, especially for the case of bolted joints made of dissimilar materials.

The performance of bolted connections can be increased with the use of elastomeric gaskets as well as with the simultaneous use of adhesive bonding. In fact, rubber components, including seals, gaskets, o-rings are important components not only for the automotive industry but for a wide range of the whole manufacturing arena. This symposium includes papers on Finite Element Analysis (FEA) based characterization of such materials including incorporation of aging and service conditions to obtain material coefficients in such analysis, and the use of compression relaxation testing in the compound development of such components. Results presented also reveal that the strength of shrink fitted joints of hollow shafts subjected to torsion is higher when adhesive bonding is incorporated along with the shrink fitting procedure.

In order to achieve efficient bonding, especially to metal substrates, the surface of the substrate must be prepared to remove weak boundary layers, improve wettability by the resin, and increase the interlocking effect by the adhesive. Different surface preparation procedures such as chemical etching, sandblasting, laser ablation applied on different substrates result in geometrically varying surface topographies. Not only the average mathematical properties of these asperities, such as the arithmetic mean roughness, mean peak-to-valley height etc., but also the shape of the asperities are expected to affect the quality of adhesion, and these issues are addressed in this symposium. Among the other novel findings reported in the arena of adhesives and adhesion are the following. It is determined that for single lap adhesive joints it may not be necessary to have the adhesive cover the whole overlap length for efficient adhesion. If the adhesive covers over half of the area from the overlap edges towards the center of the overlap, the joint strength is not different than that for a joint with full adhesive coverage. For butt joints of hollow shafts, the tensile strength increases with decreasing taper angle at the joint (i.e., departure from butt configuration, angle defined w.r.t. the loading axis). It is also determined that increasing the adhesive thickness does not result in increased damping capacity in adhesive joints.

An emerging topic in the area of lightweight composite materials is the design and Application of highly tunable composite springs. Composites present a very exciting possibility in replacing metals in helical and other geometry springs due to their promise of durability, lightweight, and the ability to closely control the mechanical and geometrical behavior. This symposium included two papers on the free vibration behavior of such springs.

The Reliability, Stress Analysis, and Failure Prevention (RSAFP) Committee of the Design Engineering Division participated in 1998 International Mechanical Engineering Congress and Exposition with a focus on adhesive joining, bolted connections, rubber components, composite springs, and fifteen papers presented in this program are contained in this volume. The sessions of the

RSAFP program were entitled:

Design, Durability, and Adhesion of Rubber Components, and Springs; Chair: Mr. A. Pannikottu;
