Permafrost Soils Rosa Margesin, 2008-10-31. Most of the Earth's biosphere is characterized by low temperatures. Vast areas, 20% of the soil ecosystem, are permanently frozen or are unfrozen for only a few weeks in summer. Permafrost regions occur at high latitudes and also at high elevations. A significant part of the global permafrost area is represented by mountains. Permafrost soils are of global interest since a significant increase in temperature is predicted for polar regions. Global warming will have a great impact on these soils, especially in northern regions, since they contain large amounts of organic carbon and act as carbon sinks, and a temperature increase will result in a release of carbon into the atmosphere. Additionally, the intensified release of the climate-relevant tracer gas methane represents a potential environmental hazard. Significant numbers of viable microorganisms, including bacteria, archaea, phototrophic cyanobacteria, and green algae, fungi, and protozoa, are present in permafrost, and the characteristics of these microorganisms reflect the unique and extreme conditions of the permafrost environment. Remarkably, these microorganisms have been reported to be metabolically active at subzero temperatures even down to 20 °C.
