Minimal Residual Disease In Melanoma Biology Detection And Clinical Relevance:

Minimal Residual Disease in Melanoma U. Reinhold, W. Tilgen, 2011-10-08 Knowledge about diagnostic procedures in melanoma has increased rapidly within the past few years. Single tumor cells have been identified in normal tissue such as sentinel lymph nodes as well as in bone marrow, peripheral blood and other bodily fluids and cells by molecular technologies. The introduction of polymerase chain reaction based methods can be regarded as a prototype of this dramatic development towards molecular approaches in new diagnostic procedures. This fact opens up the possibility of clinical use in patients and of influencing treatment strategies. Considerable discrepancies have been described however in the success rates of these new techniques for the detection of minimal residual disease in cancer patients. Despite favorable results reported by different groups of investigators it will take several years to define the clinical and pathophysiological relevance of new diagnostic procedures. The 1st International Symposium Minimal Residual Disease in Melanoma Biology Detection and Clinical Relevance of Micrometastases held in September 1999 in Homburg Saar Germany focused on recent developments in this particular area of cancer research. The purpose of the meeting was to stimulate discussion and exchange of new data and ideas by renowned international scientists. The aim of this volume is to summarize major topics of basic research and clinical investigations presented by invited experts in this fascinating but still controversial field of melanoma research.

Advances in Biology and Therapy of Multiple Myeloma Nikhil C. Munshi,Kenneth C. Anderson,2012-12-09 Despite the advances in conventional novel agent and high dose chemotherapy multiple myeloma MM remains incurable In order to overcome resistance to current therapies and improve patient outcome novel biologically based treatment approaches are being developed Current translational research in MM focusing on the development of molecularly based combination therapies has great promise to achieve high frequency and durable responses in the majority of patients Two major advances are making this goal possible First recent advances in genomics and proteomics in MM have allowed for increased understanding of disease pathogenesis identified novel therapeutic targets allowed for molecular classification and provided the scientific rationale for combining targeted therapies to increase tumor cell cytotoxicity and abrogate drug resistance Second there is now an increased understanding of how adhesion of MM cells in bone marrow BM further impacts gene expression in MM cells as well as in BM stromal cells BMSCs As a result of these advances in oncogenomics on the one hand and increased understanding of the role of the BM in the pathogenesis of MM on the other a new treatment paradigm targeting the tumor cell and its BM microenvironment to overcome drug resistance and improve patient outcome has now been developed Thalidomide lenalidomide and Bortezomib are three agents which target the tumor cell in its microenvironment in both laboratory and animal models and which have rapidly translated from the bench to the bedside Ongoing efforts are using oncogenomics and cell signaling studies to identify next generation of therapies in MM on the one hand and to inform the design of combination trials on the other This new paradigm for overcoming drug resistance and improving patient outcome in MM has great promise not only to change the natural history of MM but also to serve as a model for targeted therapeutics directed to improve outcome of patients with MM
