

The renaissance of endocrine therapy in breast cancer

Nicole Williams^a and Lynneby N. Harris^{a,b}

Purpose of review

Endocrine therapy for breast cancer has been the cornerstone of treatment for over a century since the discovery of the regressive effect of oophorectomy on 'cancer of the mamma' in 1896 by Beston. Studies in the prevention and treatment of both early and metastatic breast cancer will be reviewed with a focus on recent large randomized clinical trials that may be practice changing.

Recent findings

Data from pivotal clinical trials that looked at the duration of adjuvant hormonal therapy in premenopausal women will be discussed. In addition, several recent clinical trials that address the optimal sequence of endocrine therapy and advances in the treatment of endocrine-resistant metastatic disease will be reviewed. New findings from molecular studies that demonstrate targets in the endocrine axis and the role of aromatase inhibitors in the prevention setting will be highlighted.

Summary

Overall, these clinical trials show the benefit of aromatase inhibitors in the prevention setting, longer duration of tamoxifen in the adjuvant setting for premenopausal women, and new biologic agents with hormonal therapies.

Keywords

endogen receptors, aromatase inhibitors, endocrine therapy, mTOR inhibitors, tamoxifen

INTRODUCTION

Hormone-receptor-positive breast cancer is the most common breast cancer subtype in developed countries, regardless of the age or stage at presentation. Approximately 60% of breast cancers diagnosed in premenopausal women and 75–80% of breast cancers found in postmenopausal women are hormone receptor positive. Recent guidelines from the College of American Pathologists re-defined hormone-receptor-positive breast cancer as expressing estrogen receptor or progesterone receptor at at least 1% by immunohistochemistry [1]. Although not agreed upon by all of the academic community, these guidelines recognize the fact that even at very low levels of estrogen receptor expression, benefit is observed from antiestrogen therapy.

Endocrine therapy for breast cancer has been the cornerstone of treatment for over a century since the discovery of the regressive effect of oophorectomy on 'cancer of the mamma' by Beston in 1896 [2]. Despite its central role in treatment, and although it is indeed the first 'targeted therapy', few advances have been made until very recently. Decades of

research on endocrine resistance and discovery of new genomic targets have led to new hormonal targets, combinations of hormonal therapy with biologic agents, and with dual hormonal therapies. This is indeed a 'hormonal renaissance' for breast cancer, and not a moment too soon as much progress has been made in other breast cancer subtypes.

This review will address the recent studies in the prevention and treatment of hormone-receptor-positive breast cancer and their impact on clinical practice.
