SUMMARY

Cardiac amyloidosis is an infiltrative disease which requires a high degree of clinical suspicion for appropriate diagnosis. Early diagnosis and the definition of the type of amyloidosis play a key role in the early treatment and prognosis of this disease. In this context, the use of cardiac biomarkers such as troponins and NT-proBNP associated with analysis by multimodality imaging methods like echocardiographic techniques such as strain, nuclear medicine, and cardiovascular resonance imaging have an increasing role in patients with cardiac amyloidosis. This article details the role of non-invasive diagnostic methods in patients with cardiac amyloidosis.

KEYWORDS: Amyloidosis. Echocardiography. Magnetic resonance spectroscopy. Nuclear medicine. Biomarkers.

INTRODUCTION

Amyloidosis is a systemic disease resulting from tissue deposition of an amyloid substance. Although the heart is one of the organs most frequently affected in systemic amyloidosis, cardiac involvement is not a rule. Regardless, it is essential to identify it, since the presence of cardiac amyloidosis (CA) significantly affects the prognosis of the disease¹⁻⁴.

Clinically, it can be classified as:

1. AL amyloidosis is the most severe and common form of systemic amyloidosis. It results from the deposition of protein derived from fragments of the immunoglobulin light chain (AL amyloid). The heart

is affected in up to 90% of the patients, and only 5% have isolated heart disease⁴.

2. The hereditary amyloidosis (familial) is an autosomal dominant inheritance disease caused by tissue deposition of mutant amyloid protein derived from genetic variants of transthyretin (TTR), apolipoprotein A-I, lysozyme or fibrinogen alpha chain. The heart is most commonly involved with the mutation of TTR (ATTR amyloidosis)⁵.

3. The senile systemic amyloidosis (or wild type) results from the deposition of amyloid proteins derived from wild type transthyretin (TTR wt). It occurs more

Noninvasive Cardiac Electrophysiology Marek Malik, Federico Lombardi, Georg Schmidt, Richard Leonard Verrier, 2021-07-02 Effective identification of patients at increased risk of malignant cardiac arrhythmia presently represents a clinically important unmet need Existing guidelines for the selection of candidates for the prophylactic implantation of cardioverters defibrillators ICD are based solely on the reduction of ventricular haemodynamic performance Although this guidance is based on statistical results of previously conducted randomized clinical trials available experience shows that it does not serve clinical needs efficiently The majority of patients who are implanted with ICDs for prophylactic reasons never utilize the device during its technical longevity whilst at the same time many patients who succumb to sudden cardiac death do not have ventricular haemodynamic performance particularly compromised Recent results also showed that the previous statistical findings of ICD efficacy are not fully reproducible in patients with non ischemic heart disease and that the reduction of sudden cardiac death after myocardial infarction by external automatic defibrillation vests is lower than expected Advances in cardiac electrophysiology are needed for better understanding of the mechanisms that are the basis of different arrhythmic abnormalities Increased understanding of these mechanisms will allow them to be more effectively classified so that optimum therapeutic options can be offered Likewise better understanding of the underlying

electrophysiology processes is needed so that novel and more focused randomized clinical trials can be designed Compared to invasive electrophysiological studies noninvasive cardiac electrophysiology offers the possibility of screening larger number of patients as well as healthy subjects investigated under different provocations and conditions To advance the field broad spectrum of studies is needed together with meta analyses and reviews facilitating research interactions

Integrated Non-Invasive Cardiovascular Imaging: A Guide for the Practitioner IAEA,2021-06-14 Integrated cardiovascular imaging is the optimal use of multiple imaging modalities to obtain complementary information about cardiac diseases to aid in diagnosis determine aetiology and prognosis with the ultimate objective of effectively guiding clinical decision making Over the past few decades advances in technology have contributed to the development of new imaging modalities and refinement of existing ones leading to major improvements in the accuracy of diagnosing cardiovascular disease While modality centric expertise has been the primary driver of improvements in each modality this has also contributed to imagers working in silos resulting with limited inter modality coordination and collation of information relevant for patient care This publication provides comprehensive guidance on the rationale and implementation of integrated cardiovascular imaging for practitioners
