*The Retinal Pigment Epithelium* Michael F. Marmor, Thomas J. Wolfensberger, 1998 The retinal pigment epithelium is a critical tissue within the eye It lies directly behind the retina where it provides metabolic support to the photoreceptors and controls their local environment As a result the RPE is vital to retinal function but also a site of aging and disease that cause dysfunction and visual loss This book brings together comprehensive reviews of basic and clinical science concerning the RPE It is organized to juxtapose chapters on RPE disease with chapters on the underlying pathophysiology These include up to date accounts of growth factors laser effects proliferative vitreoretinopathy Bruch s membrane pathology as well as new diagnostic tools such as ocular coherence tomography in vivo imaging of lipofuscin and non photic electrical responses Other chapters cover pharmacology and toxicology mechanisms of retinal adhesion and detachment RPE pigments and transport congenital and dystrophic diseases animal models of RPE disease and different aspects of age related macular degeneration The history and evolutionary aspects of the RPE are also presented The contributing authors are experienced clinicians and eminent basic scientists who work on this critical part of the eye The book will be a valuable resource for anyone interested in the eye and a necessity for specialists in the fields of retinal physiology and retinal disease **Retinal Pigment**

*Ocular Transporters in Ophthalmic Diseases and Drug Delivery* Joyce Tombran-Tink, Colin J. Barnstable, 2008-04-09 Detection and responses to light are common features

found throughout the plant and animal kingdoms In most primitive life forms a patch of light sensitive cells make up a region containing a cell sheet devoid of any specialized anatomical structure With the development of the eyes in more advanced life forms light sensing structures became more complex but primitive eyes are still in contiguity with other body tissues and fluids The evolution of the eyeball promoted an increase in visual acuity and visual processing that in turn allowed vision to become the dominant sensory system for many species including humans The formation of a totally enclosed structure however required a unique set of solutions to enable the eye to control its environment Like most organs the eye evolved a series of homeostatic mechanisms to regulate its environment within tightly controlled limits Unlike most organs however this advanced light sensing structure has a series of requirements that place a tremendous burden on molecules that are responsible for controlling ocular homeostasis There are many signaling molecules and pathways that work in parallel or through crosstalk to maintain the normal ocular environment required for visual function Perhaps none are so critical as the group of membrane molecules that are collectively termed transporters These molecules are responsible for the controlled and selective movements of ions nutrients and fluid across various ocular layers necessary to optimize the internal milieu to preserve visual function
