

Igneous Rocks

Igneous rocks are created from magma, which is molten rock. The name itself tells you it's liquid, which is where the word igneous gets its name. Igneous rocks can be formed in two different ways: under the Earth's surface (intrusive) or above the Earth's surface (extrusive) or along the Earth's surface (volcanic).

There are many different types of igneous rock. Some of the most common are basalt, andesite, rhyolite, granite, gneiss, and obsidian.

Basalt

Basalt is one of the most common types of igneous rock. It has a dark, glassy look, and it is the second most common of all the different igneous rocks. Basalt is formed from extremely hot, molten magma that cools very quickly (extrusive). Basalt is usually found in volcanic eruptions, which help explain how hot and how the magma becomes.

Andesite

Andesite is a medium gray, blocky rock, it is formed by molten magma (extrusive) that cools very slowly. This rock is extrusive from a magma chamber that is a little closer to the surface than basalt eruptions. The magma from this eruption is a little more viscous (sticky) and is hot. This means the rock is firm and makes a strong sound.

Rhyolite

Rhyolite is a light-colored rock, generally lighter in weight than other igneous rocks. Rhyolite is formed from the surface of a volcanic eruption. The magma chamber of a volcanic eruption is located close to the Earth's surface, and the magma that cools is very hot and sticky. The magma that cools makes the rhyolite, making it possible when it erupts. Rhyolite is a well-known type of igneous rock.

Igneous Rocks

Basalt

Basalt is an extrusive or volcanic igneous rock. This means it is created by molten magma under the surface of the Earth. Basalt is formed by slowly cooling magma, which forms large crystals in it. Basalt can look quite different depending on the different shapes and colors of the crystals that are formed.

Andesite

Andesite is usually a volcanic glass. It is usually dark and very shiny. Because basalt rock cools extremely slowly, forms andesite. It is a dark rock because there is no gas or water in the lava when it solidifies. Andesite is usually formed when a volcanic eruption erupts.

Rhyolite

Rhyolite is one of the most common rocks you may find, and you might not even think it is a rock! It is very light and full of holes. Rhyolite is a type of igneous rock. It forms when molten lava cools quickly, trapping air inside. Rhyolite is found where a volcanic eruption erupts.

Volcanic Eruptions

Lake Taupō in the center of New Zealand is an important lake. It is also a volcanic eruption.

When Lake Taupō erupted around 1800 years ago, its eruption was so big that the forests and fields were not saved from the ash that it threw into the sky. That means that the ash from the eruption must have covered the whole forest.

Volcanic eruptions can be very dangerous because they can cause volcanic eruptions from the surface, making it difficult for people to pass through.
