Regulation

of Hepatic Metabolism K. Jungermann, F.C. Kauffman, R.G. Thurman, 2012-12-06 The liver is an exceptionally complex and diverse organ that functions both as an exocrine and an endocrine gland It secretes bile which contains many constituents in addition to bile salts and it synthesizes and releases many substances in response to the body's demands including prohormones albumin clotting factors glucose fatty acids and various lipoproteins It has a dual blood supply providing a rich mixture of nutrients and other absorbed substances via the portal vein and oxygen rich blood via the hepatic artery This functional heterogeneity is accompanied by cellular heterogeneity The liver contains many cell types including hepatic parachymal cells Kiipffer cells Ito cells and endothelial cells The most abundant cell type the parenchymal cells are biochemically and structurally heterogeneous The cells in the oxygen rich areas of the portal triad appear more dependent on oxidative metabolism whereas those around the central vein pericentral perivenous or centrolobular areas are more dependent upon an anaerobic mechanism Throughout this volume the latter three terms are used synonymously by various authors to indicate the five to eight layers of cells radiating from the central vein Structural and metabolic heterogeneity of hepatic parenchymal cells has been demonstrated by a variety of approaches including histochemical ultra structural and ultramicrobiochemical studies This microheterogeneity is linked to the physiological functions of the liver and its response to injurious substances
