micrometers. Further, in the winter the measured bubble population in the ocean is one order of magnitude less than in the summer. We see then it is actually possible for laboratory facilities to have much higher nuclei populations than actually occur in the ocean. Medwin concludes interestingly that the microbubbles had a biological as well as physical origin because the concentration of bubbles increased with depth. This observation is perhaps of importance for the Coulter Counter measurements of Peterson (1974) and Lang (1977). The particulates measured there, although thought to be of organic material, may actually also contain some gas. Finally, it is amazing to observe the wide range of applicability of fairly simple power laws for particulate and microbubble populations.

9. CONCLUSIONS

It is clear that the onset of cavitation and its physical appearance at this onset can be greatly affected by freestream turbulence and the presence of minute amounts of long chain polymer solutes. The present results support the conclusion that these effects are indirect insofar as cavitation goes and that the primary effect is on the viscous flow past the test body. The polymer solutions in particular promote an early boundary layer transition which forestalls the presence of laminar separation such as does boundary layer stimulation by freestream turbulence or trips. It follows that cavitation on bodies not having laminar separation
