Quantitative Electron Microscopy Intersociety Committee for Research Potential in Pathology, Armed Forces Institute of Pathology (U.S.), 1965      **Quantitative Electron Microscopy of Supported Subnanometer Clusters** Ajay Singhal, 1996 Small supported particles a few angstroms in diameter are useful as catalysts because of their increased surface area for a given volume of material Their catalytic activity and selectivity depends upon their size which determines their electronic structure Therefore it is vital to reliably understand particle size distribution and variation which occurs due to

fragmentation and sintering In this research I present a refined electron microscopy approach to study particle size distributions and use this to investigate the stability of very small cluster rhenium supported on graphite Z contrast microscopy using a scanning transmission electron microscope STEM has had significant influence on the study of ultra small supported particles However the importance of suppressing longitudinal coherence was not fully recognized until recently Therefore the Z contrast atomic number method remained less quantitative Present work fills this gap by employing very high angles of scattering in annular dark field STEM imaging of small rhenium particles At high scattering angles intra columnar diffraction from the atoms in a crystal is suppressed significantly This ensures a linear rise of the scattered intensity with the number of atoms in a given metal particle Absolute measurements of elastically scattered electron intensity were performed for graphite supported rhenium clusters comprising less than ten metal atoms Measured cross sections show good agreement with theoretically calculated values We use the method to demonstrate exceptional stability of the 6 Re organometallic clusters over other sizes such as 8 Re particles These measurements require careful STEM detector calibration In addition attention must be paid to preparation of well dispersed particles suitable for statistical analysis
