**Abstract.** The overview covers selected topics on magnetic dichroism in atomic core level photoemission: the geometrical model in photoionization of laser polarized atoms and its generalization, contributions to the complete experiment from magnetic dichroism studies and nondipole effects in magnetic dichroism.

## 1 Introduction

The term ‘dichroism’ is generally used to reflect the dependence of photon interaction with a material on the polarization of the photon and on the anisotropy of the material. One speaks about ‘magnetic’ dichroism (MD) when its origin is in the latter. The MD with circularly and linearly polarized radiation is called circular magnetic dichroism (CMD) and linear magnetic dichroism (LMD), respectively. A rapid progress in the VUV and X-ray CMD and LMD studies was stimulated by the advent of new high-brilliance synchrotron radiation (SR) sources with controlled variable polarization. In solids and nanoobjects, MD in photoabsorption near the core level ionization thresholds, accompanied by remarkable theoretical developments, provides valuable information on the element-specific magnetic structure and has become a magnetometry tool (e.g. [1–3] and references therein). In the photoionization region, new aspects of the MD come up associated with a new degree of freedom, namely the escape direction of the photoelectron. Besides, in contrast to photoabsorption, the final wave function is a scattering state, leading to complex amplitudes with non-zero relative phases. These two important points increase the potential of the MD method, in particular an analysis of the CMD and LMD in the angular distribution of the photoelectrons (CMDAD and LMDAD, respectively) becomes possible (e.g. [4–7] and references therein).

Another class of VUV and X-ray MD studies deals with atoms in the gas phase. In practice, the target atom polarization, which is an analogue of magnetization in solid materials, can be induced by photoabsorption, optical laser pumping, or an inhomogeneous external magnetic field. Photoionization of the polarized atoms is an important tool to investigate subtle details of the photoionization dynamics, reaching the stage of a complete quantum mechanical experiment. From another side, as a consequence of the localized character of the core electrons, the atomic picture of core level photoemission can serve as a reasonable first approximation for the photoemission from solid samples and films. Comparison of photoemission from atoms and condensed materials open an access to separate intra-atomic and interatomic effects in the spectra of bound atoms.

The combination of optical laser pumping and intense SR resulted in a breakthrough in investigations of MD in gaseous atomic targets [8–11]. High intensity of the SR permits to decrease the atomic density in the reaction volume and therefore to avoid collisions and radiation trapping, which destroy the target polarization. Furthermore, the energy resolution improved
