**Abstract**—System security continues to be of increasing importance. To effectively address both natural and intentional threats to large systems, the threats must be cataloged and analyzed. Extremely large and complex systems can have an accordingly large number of threat scenarios. Simply listing the threats and devising countermeasures for each is ineffective and not efficient. We describe a threat cataloging methodology whereby a large number of threats can be efficiently cataloged and analyzed for common features. This allows countermeasures to be formulated that address a large number of threats that share common features. The methodology utilizes Multiple-Valued Logic for describing the state of a large system and a multiple-valued decision diagram (MDD) for the threat catalog and analysis.

## I. INTRODUCTION

In recent years, more emphasis has been placed on design for security, security assessment, disaster recovery, disaster tolerance, in addition to the ongoing efforts in the established areas in fault tolerance. All of these areas require the identification and analysis of faults or threats. Most fault models and analysis methods assume that a fault causes a system to either function or fail and are thus modeled with binary conditions.

Recent events have demonstrated our vulnerability to disasters, both natural and man-made. This motivates the need to incorporate disaster tolerance into large system designs. Disaster tolerance is a superset of the more established approaches commonly referred to as fault tolerance. Models for disaster tolerance differ from those for fault tolerance since they assume that failures can occur due to single or massive numbers of individual faults occurring simultaneously or in a rapidly cascading manner. Traditional fault tolerance models single points of failure. Therefore, a disaster-tolerant system can withstand a catastrophic failure and still function with some degree of normality [8, 15].

Threats on a system can include both accidental and intentional effects. Examples of accidental events include random component failures, natural disasters, and fires. Examples of intentional effects include sabotage and cyber threats. A variety of tree structures have been developed to represent possible system threats. These tree structures are

commonly called fault trees or attack trees. Fault trees were originally developed to identify the effects of component failures on a system [16] while attack trees traditionally focused on the effects of cyber security breaches [14]. There have been recent variants of these trees, and sometimes these trees have been used interchangeably [2, 5, 6, 7, 11]. However, these trees all have one thing in common: they are binary-valued trees, connected with AND and OR operators. This limits the effectiveness of how they can represent possible system-wide attacks. Modeling different operational modes other than just the binary case of failure or normal operation are critical in analyzing large systems in the presence of threats. As an example, in the 2003 blackout of the US power grid, many complex interactions caused a blackout to occur in a large portion of the northeastern US; however, it would be incorrect to state that the entire US power grid failed. In order to effectively catalog system threats, it is necessary to determine the probabilities of these threats based on various system stimuli, including input conditions and their probabilities.

As part of our preliminary research on large-scale system threat assessment, we developed threat tree models [12]. Threat trees are a superset of fault and attack trees since they are based on multiple-valued (MV) or radix- $p$  valued algebras over a finite and discrete set of values [10]. When the radix  $p=2$ , the threat tree reduces to a fault or attack tree depending on the nature of the disruptive events. Generally, threat trees have  $p>2$ ; these additional logic states allow for more complicated interactions to be modeled. In particular, these additional states can represent partial failures or degraded performance in a system, which are critical in analyzing large systems in the presence of threats.

The structure of this paper is the following: First, background information on decision diagram models is provided. Next, an approach is presented using decision diagram models to determine system threat probabilities. Finally, a system example is used to illustrate these concepts.

## II. DECISION DIAGRAMS

Fig. 1 shows an example of a simple binary fault tree where the circular nodes represent the event of a single component failure and the logic operators (AND/OR gates) show how the events combine to result in a subsystem failure. Referring to
