

The oxidized fragments formed from a particular alkene structure can be predicted by applying a few simple rules. Indeed, by characterizing the structure of the oxidation fragments it is often possible to test backwards to establish the structure of the alkene. This was an important method for alkene structure determination prior to the advent of modern instrumental methods. The mechanistic details of these reactions need not concern us at this time, but the cleavage rules and products should be memorized.

OXIDATIVE CLEAVAGE RULES

Hot Permanganate Oxidation

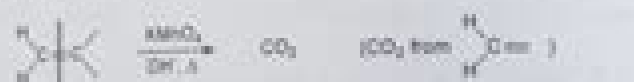

Fig. 26-4 Oxidative cleavage of alkenes by hot permanganate.

Cold Oxidation

Fig. 26-5 Oxidative cleavage of alkenes by ozone.

Here are a few specific examples of alkene oxidation:

Reactions of Alkynes

Alkynes, having carbon-to-carbon triple bonds, can undergo much the same type of addition and oxidative reactions as alkenes, although with some easily understood differences. Each mole of an alkyne can add two moles of various reagents, since they possess two π bonds, while alkenes only have one. This is possible to add two moles of H_2 , halogen acids, H_2O , etc., to alkynes. Oxidative cleavage reactions of alkynes produce fragments in a higher oxidation state than alkenes. The products from alkynes are carboxylic acids using either hot permanganate or ozone. One most interesting difference is the hydration (addition of water) of alkynes (a reaction catalyzed by Hg^{2+}), usually produces a vinyl alcohol. (The same reaction of water) of alkenes (a reaction catalyzed by Pt^{2+}), usually produces a *tert*-alcohol. (The same reaction to a group bonded directly to an alkene carbon atom.) Most vinyl alcohols spontaneously rearrange to a ketone, thus the isolated hydration product of an alkyne is a ketone. This rearrangement is called
