Some parasitic diseases, such as malaria, require two hosts to complete their lifecycle: a human and an insect vector. Although most malaria research has focused on parasite development in the human host, the life cycle within the vector is critical for the propagation of the disease. The mosquito stage of the *Plasmodium* lifecycle represents a major demographic bottleneck, crucial for transmission blocking strategies. Furthermore, it is in the vector, where sexual recombination occurs generating “de novo” genetic diversity, which can favor the spread of drug resistance and hinder effective vaccine development. However, understanding of vector-parasite interactions is hampered by the lack of experimental systems that mimic the natural environment while allowing to control and standardize the complexity of the interactions. The breakthrough in stem cell technologies has provided new insights into human-pathogen interactions, but these advances have not been translated into insect models. Here, we review *in vivo* and *in vitro* systems that have been used so far to study malaria in the mosquito. We also highlight the relevance of single-cell technologies to progress understanding of these interactions with higher resolution and depth. Finally, we emphasize the necessity to develop robust and accessible *ex vivo* systems (tissues and organs) to enable investigation of the molecular mechanisms of parasite-vector interactions providing new targets for malaria control.

KEYWORDS

mosquito, *Plasmodium*, organoids, tissue explant, membrane feeding assay (MFA), Anopheles

1 Introduction

Mosquitoes are responsible for the transmission of many life-threatening diseases, causing millions of deaths every year. Malaria is one of the deadliest infectious diseases affecting half of the world's population and causing over half a million deaths per year (WHO, 2022). It is caused by apicomplexan parasites of the *Plasmodium* genus and is transmitted by the bite of a female *Anopheles* mosquito. The parasite survival in the mosquito is necessary for the spread of malaria and is therefore a target for the development of transmission blocking strategies (Yu et al., 2022).

Novel Perspectives of Stem Cell Manufacturing and Therapies Diana Kitale,Ana Colette Maurício,2021-04-14 In the 1950s Nobel Prize winner Dr E Donnall Thomas was the first to successfully transplant hematopoietic stem cells Since then studies on stem cells have evolved and expanded worldwide There are more than 650 000 scientific publications on stem cells and more than 8000 stem cell clinical trials This book summarizes types of stem cells key studies ongoing trials and future perspectives It also includes ethical formal and legal aspects to give the reader a comprehensive view of the field

Humanized Mice Tatsuji Nomura,Takeshi Watanabe,Sonoko Habu,2008-03-11 The term humanized mouse in this text refers to a mouse in which human tissues and cells have been transplanted and show the same biological function as they do in the human body That is the physiological properties and functions of tra planted human tissues and cells can be analyzed in the mouse instead of

using a living human body It should therefore be possible to study the pathophysiology and treatment of human diseases in mice with good reproducibility Thus the humanized mouse can be used as a potent tool in both basic and clinical research in the future The development of appropriate immunodeficient mice has been indispensable in the creation of the humanized mouse which has been achieved through many years of efforts by several laboratories The first stage on the road to the humanized mouse was the report on nude mice by Isaacson and Cattaneach in 1962 Thereafter nude mice were studied in detail by Falandan and in 1968 Pantelouris found that these mice have no thymus gland which suggested that the mice lack transplantation immunity against xenografts such as human hematopoietic stem cells At the Nude Mouse Workshops organized by Regard Povlsen Nomura and colleagues that were held nine times between 1972 and 1997 the possibility of creating a humanized mouse using nude mice was extensively examined The results however showed that certain human cancers can be engrafted in nude mice but unfortunately engraftment of normal human tissue was almost impossible
